## Problem

tl;dr: Given a string of digits  $S$ , insert a minimum number of opening and closing parentheses into it such that the resulting string is balanced and each digit  $d$  is inside exactly  $d$  pairs of matching parentheses.

Let the *nesting* of two parentheses within a string be the substring that occurs strictly between them. An opening parenthesis and a closing parenthesis that is further to its right are said to *match* if their nesting is empty, or if every parenthesis in their nesting matches with another parenthesis in their nesting. The *nesting depth* of a position  $p$  is the number of pairs of matching parentheses  $m$  such that  $p$  is included in the nesting of  $m$ .

For example, in the following strings, all digits match their nesting depth:  $\emptyset((2)1)$ ,  $((3))1(2))$ ,  $((4)))$ ,  $((2))((2))(1)$ . The first three strings have minimum length among those that have the same digits in the same order, but the last one does not since  $((22)1)$  also has the digits 221 and is shorter.

Given a string of digits  $S$ , find another string  $S'$ , comprised of parentheses and digits, such that:

- all parentheses in  $S'$  match some other parenthesis,
- removing any and all parentheses from  $S'$  results in  $S$ ,
- each digit in  $S'$  is equal to its nesting depth, and
- $S'$  is of minimum length.

## Input

The first line of the input gives the number of test cases,  $T$ .  $T$  lines follow. Each line represents a test case and contains only the string  $S$ .

## Output

For each test case, output one line containing Case # $x$ :  $y$ , where  $x$  is the test case number (starting from 1) and  $y$  is the string  $S'$  defined above.

## Limits

Time limit: 20 seconds per test set.

Memory limit: 1GB.

$1 \leq T \leq 100$ .

$1 \leq \text{length of } S \leq 100$ .

## Test set 1 (Visible Verdict)

Each character in  $S$  is either 0 or 1.
